Some linear algebra

## 3. Tensors and exterior forms 3.1. Some linear algebra

We start with a reminder on some basic operations on vector spaces. For simplicity, all vector spaces will be finite-dimensional over  $\mathbb{R}$ . If U is a vector space, the *dual vector space* is  $U^* = \operatorname{Hom}(U, \mathbb{R})$ , with dim  $U^* = \dim U$ . If  $u^1, \ldots, u^m$  is a basis of U, there is a dual basis  $u_1, \ldots, u_m$  of  $U^*$ , with  $u_i(u') = \delta_{ii}$  for  $i, j = 1, \ldots, m$ . We can identify  $U = (U^*)^*$ . If U, V are vector spaces, the *direct sum* is  $U \oplus V = U \times V = \{(u, v) : u \in U, v \in V\}.$ 

It is a vector space of dimension dim  $U + \dim V$ . If  $u^1, \ldots, u^m$  and  $v^1, \ldots, v^n$  are bases of U, V, then  $u^1, \ldots, u^m, v^1, \ldots, v^n$  is a basis of  $U \oplus V$ . So we can *add vector spaces*. Direct sum is associative and commutative,  $U \oplus V = V \oplus U$ ,  $U \oplus (V \oplus W) = (U \oplus V) \oplus W$ .

We can also *multiply vector spaces*. For U, V vector spaces, the *tensor product*  $U \otimes V$  is a natural vector space with  $\dim(U \otimes V) = \dim U \cdot \dim V$ . There is a bilinear operation

 $\otimes: U \times V \longrightarrow U \otimes V, \quad (u, v) \longmapsto u \otimes v.$ 

If  $u^1, \ldots, u^m$  and  $v^1, \ldots, v^n$  are bases of U, V, then  $\{u^i \otimes v^j : i = 1, \dots, m, j = 1, \dots, n\}$  is a basis of  $U \otimes V$ . Formally, we may define

 $U \otimes V = \{ \text{bilinear maps } \alpha : U^* \times V^* \longrightarrow \mathbb{R} \},\$ 

and for  $u \in U$ ,  $v \in V$ , define  $u \otimes v \in U \otimes V$  to be the bilinear map

 $u \otimes v : U^* \times V^* \longrightarrow \mathbb{R}, \quad u \otimes v : (\alpha, \beta) \longmapsto \alpha(u) \cdot \beta(v).$ 

Tensor products are associative and commutative and distributive over direct sum,  $U \otimes V = V \otimes U$ ,  $U \otimes (V \otimes W) = (U \otimes V) \otimes W$ ,  $U \otimes (V \oplus W) = (U \otimes V) \oplus (U \otimes W)$ , just as you would expect.

Exterior forms Symmetric and exterior (antisymmetric) products Let V be a vector space. Then we can form the *n*-fold tensor  $\ \sqcap n \text{ copies } \urcorner$ product  $\bigotimes^n V = V \otimes \cdots \otimes V$ . The symmetric group  $S_n$  acts on  $\bigotimes^n V$  by permutations on the *n* factors, so that  $\sigma \in S_n$  acts by  $\sigma: v_1 \otimes \cdots \otimes v_n \longmapsto v_{\sigma(1)} \otimes \cdots \otimes v_{\sigma(n)}$ for  $v_1, \ldots, v_n \in V$ . The *n*<sup>th</sup> symmetric power  $S^nV$  is the subspace of  $\bigotimes^n V$  invariant under  $S_n$ , with  $\dim S^n V = \begin{pmatrix} \dim V + n - 1 \\ n \end{pmatrix}$  $S^n V = \{ \mathbf{v} \in \bigotimes^n V : \sigma(\mathbf{v}) = \mathbf{v} \text{ for all } \sigma \in S_n \}.$ The  $n^{th}$  exterior power  $\Lambda^n V$  is the subspace of  $\bigotimes^n V$ anti-invariant under  $S_n$ , with  $\dim \Lambda^n V = \begin{pmatrix} \dim V \\ n \end{pmatrix}$  $\Lambda^n V = \{ \mathbf{v} \in \bigotimes^n V : \sigma(\mathbf{v}) = \operatorname{sign}(\sigma) \mathbf{v} \text{ for all } \sigma \in S_n \}.$ For n = 2 we have  $\bigotimes^2 V = S^2 V \oplus \Lambda^2 V$ . We can identify  $\bigotimes^2 \mathbb{R}^n$  with  $n \times n$  matrices,  $S^2 \mathbb{R}^n$  with symmetric matrices, and  $\Lambda^2 \mathbb{R}^n$  with antisymmetric matrices. Dominic Joyce, Oxford University Lecture 3: Tensors 5/34

Tensors

Some linear algebra

Index notation for tensors

**Tensors** Exterior forms Some linear algebra Operations on vector bundles; tenso Index notation for tensors The Lie bracket of vector fields Exponentiating vector fields

## Symmetric and exterior products

There are projections  $\Pi^S : \bigotimes^n V \to S^n V$  and  $\Pi^{\Lambda} : \bigotimes^n V \to \Lambda^n V$ by symmetrization and antisymmetrization, given by

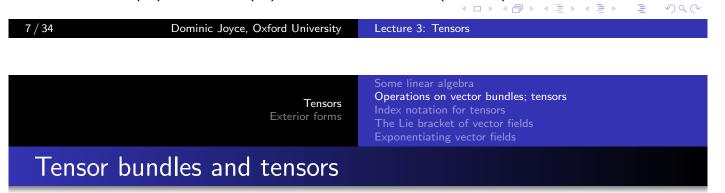

$$\Pi^{S}(\boldsymbol{v}) = \frac{1}{n!} \sum_{\sigma \in S_{n}} \sigma(\boldsymbol{v}), \quad \Pi^{\Lambda}(\boldsymbol{v}) = \frac{1}{n!} \sum_{\sigma \in S_{n}} \operatorname{sign}(\sigma) \sigma(\boldsymbol{v}).$$

The symmetric product  $\odot$  is tensor product  $\otimes$  followed by symmetrization  $\Pi^S$ , so for example  $v_1 \odot \cdots \odot v_n = \Pi^S(v_1 \otimes \cdots \otimes v_n)$  for  $v_1, \ldots, v_n \in V$ . The exterior product or wedge product  $\land$  is tensor product  $\otimes$ followed by antisymmetrization  $\Pi^{\Lambda}$ , so for example we have  $\land : \Lambda^m V \times \Lambda^n V \to \Lambda^{m+n} V$ ,  $\alpha \land \beta = \Pi^{\Lambda}(\alpha \otimes \beta)$ .

Both  $\odot$ ,  $\land$  are associative. We have  $\beta \odot \alpha = \alpha \odot \beta$  and  $\beta \land \alpha = (-1)^{\deg \alpha \deg \beta} \alpha \land \beta$ .

## 3.2. Operations on vector bundles; tensors

Now let X be a smooth manifold, and as in §1.5 consider vector bundles  $E \to X$ ,  $F \to X$ , so that for all  $x \in X$  the fibres  $E_x$ ,  $F_x$  are vector spaces. The operations on vector spaces in §3.1 all make sense for vector bundles. So we can form the *dual vector bundle*  $E^*$  with rank  $E^* = \operatorname{rank} E$  and fibres  $(E^*)_x = (E_x)^*$ , the *direct* sum vector bundle  $E \oplus F \to X$ , with rank $(E \oplus F) = \operatorname{rank} E + \operatorname{rank} F$  and fibres  $(E \oplus F)_x = E_x \oplus F_x$ , the *tensor product bundle*  $E \otimes F \to X$ , with rank $(E \otimes F) = \operatorname{rank} E \cdot \operatorname{rank} F$  and fibres  $(E \otimes F)_x = E_x \otimes F_x$ . Given  $E \to X$ , we can form the *n*-fold tensor product  $\bigotimes^n E \to X$ , the *n*<sup>th</sup> symmetric power  $S^n E \to X$  and the *n*<sup>th</sup> exterior power  $\Lambda^n E \to X$ , with fibres  $\bigotimes^n (E_x), S^n (E_x), \Lambda^n (E_x)$ . We can take direct sums and tensor products of sections: if  $e \in C^{\infty}(E)$ ,  $f \in C^{\infty}(F)$  then  $e \oplus f \in C^{\infty}(E \oplus F)$ , and so on.

As in §2.1, any manifold X has two natural vector bundles, the tangent bundle  $TX \to X$  and cotangent bundle  $T^*X \to X$ . So we can make many more bundles by direct sums, tensor products, symmetric products, and exterior products, of  $TX, T^*X$ . The *tensor bundles* on X are  $\bigotimes^k TX \otimes \bigotimes^l T^*X$  for  $k, l \ge 0$  (where if k = 0 or l = 0 we omit that term). They are vector bundles on X, of rank  $(\dim X)^{k+l}$ . A *tensor* T on X is a smooth section of some tensor bundle,

 $T \in C^{\infty}(\bigotimes^k TX \otimes \bigotimes^l T^*X).$ 

This is very general, and includes many interesting geometric structures.

ome linear algebra Operations on vector bundles; tensors

## Examples of interesting classes of tensors

### Example

A vector field v on X is a section of TX. This is a tensor with k=1 and l=0.

#### Example

An *I*-form for  $I \ge 0$ , or exterior form, on X, is a section of  $\Lambda^{T} T^*X$ . As rank  $\Lambda^{I}T^{*}X = \begin{pmatrix} \dim X \\ I \end{pmatrix}$ , this is only nonzero for  $I = 0, \ldots, \dim X$ . Since  $\Lambda' T^* X$  is a subbundle of  $\bigotimes^{I} T^{*}X = \bigotimes^{0} TX \otimes \bigotimes^{I} T^{*}X$ , *I*-forms are tensors with k = 0.

#### Example

A Riemannian metric g is a smooth section of  $S^2T^*X$  such that  $|g|_x \in S^2 T_x^* X$  is a positive definite quadratic form on  $T_x X$  for all  $x \in X$ . As  $S^2T^*X \subset \bigotimes^2 T^*X$ , this is a tensor with k = 0, l = 2.

## 3.3. Index notation for tensors

Here is some useful notation for tensors, introduced by physicists. Let X be an *n*-manifold, and  $T \in C^{\infty}(\bigotimes^k TX \otimes \bigotimes^l T^*X)$  a tensor of type (k, l) on X. Let  $(x^1, \ldots, x^n)$  be local coordinates on an open set  $U \subseteq X$ . (For consistent notation, we use superscripts  $x^i$  rather than subscripts  $x_i$ ;  $x^i$  means the  $i^{th}$  variable, not a power of x.) Then  $\frac{\partial}{\partial x^1}, \ldots, \frac{\partial}{\partial x^n}$  are a basis of sections of TX on U, and  $dx^1, \ldots, dx^n$  a basis of sections of  $T^*X$  on U. Hence we may write

$$T|_{U} = \sum_{\substack{a_{1},...,a_{k}=1,...,n\\b_{1},...,b_{l}=1,...,n}} T_{b_{1}b_{2}\cdots b_{l}}^{a_{1}a_{2}\cdots a_{k}} \frac{\partial}{\partial x^{a_{1}}} \otimes \cdots \otimes \frac{\partial}{\partial x^{a_{k}}} \otimes \mathrm{d}x^{b_{1}} \otimes \cdots \otimes \mathrm{d}x^{b_{l}}.$$
 (3.1)

Here  $T^{a_1a_2\cdots a_k}_{b_1b_2\cdots b_l}: U \to \mathbb{R}$  is a smooth function for all values of  $a_1,\ldots,a_k,b_1,\ldots,b_l\in\{1,\ldots,n\}.$ 

Thus, on U the tensor T is uniquely determined by the real functions  $T_{b_1\cdots b_l}^{a_1\cdots a_k}$  for all  $a_i, b_j$ , and vice versa. So we can identify Twith such  $n^{k+l}$ -tuples of functions  $(T_{b_1\cdots b_l}^{a_1\cdots a_k})_{b_1,\dots,b_l=1,\dots,n}^{a_1,\dots,a_k=1,\dots,n}$ , which we can think of as a kind of generalized matrix. If  $(\tilde{x}^1,\dots,\tilde{x}^n)$  is another coordinate system on  $\tilde{U} \subseteq X$ , and  $\tilde{T}_{b_1\cdots b_l}^{a_1\cdots a_k}$ the corresponding functions from  $T|_{\tilde{U}}$ , then using  $\frac{\partial}{\partial \tilde{x}^l} = \sum_{j=1}^n \frac{\partial x^j}{\partial \tilde{x}^l} \cdot \frac{\partial}{\partial x^j}$ ,  $d\tilde{x}^i = \sum_{j=1}^n \frac{\partial \tilde{x}^i}{\partial x^{ij}} \cdot dx^j$ , on  $U \cap \tilde{U}$  we have  $\tilde{T}_{b_1\cdots b_l}^{a_1\cdots a_k} = \sum_{\substack{c_1,\dots,c_k=1,\dots,n\\d_1,\dots,d_l=1,\dots,n}} \frac{\partial \tilde{x}^{a_1}}{\partial x^{c_1}} \cdots \frac{\partial \tilde{x}^{a_k}}{\partial x^{c_k}} \cdot \frac{\partial x^{d_1}}{\partial \tilde{x}^{b_1}} \cdots \frac{\partial x^{d_l}}{\partial \tilde{x}^{b_l}} \cdot T_{d_1\cdots d_l}^{c_1\cdots c_k}$ . (3.2)

This tells you how the tuples  $(T_{b_1\cdots b_l}^{a_1\cdots a_k})_{b_1,\dots,b_l=1,\dots,n}^{a_1,\dots,a_k=1,\dots,n}$  transform under change of coordinates.

Upper indices  $T^a$  are called *contravariant* (vector) indices. Lower indices  $T_b$  are called *covariant* (1-form) indices.

11 / 34	Dominic Joyce, Oxford University	Lecture 3: Tensors
	<b>Tensors</b> Exterior forms	Some linear algebra Operations on vector bundles; tensors Index notation for tensors The Lie bracket of vector fields Exponentiating vector fields

In the index notation, we write the tensor T (on all of X, not just on one coordinate chart  $U \subseteq X$ ) as  $T_{b_1 \cdots b_l}^{a_1 \cdots a_k}$ . We could interpret this in several ways. We could view it just as a formal symbol, telling us that T is a section of  $\bigotimes^k TX \otimes \bigotimes^l T^*X$ . Or, we could understand it to mean 'every time we have coordinates  $(x^1, \ldots, x^n)$ on  $U \subseteq X$ , then we get an  $n^{k+l}$ -tuple  $(T_{b_1 \cdots b_l}^{a_1 \cdots a_k})_{b_1, \ldots, b_l=1, \ldots, n}^{a_1 \cdots a_k}$  of smooth functions  $T_{b_1 \cdots b_l}^{a_1 \cdots a_k} : U \to \mathbb{R}$  as in (3.1), and under change of coordinates, these  $n^{k+l}$ -tuples transform as in (3.2)'.

## Examples of tensor notation

#### Example

A vector field v on X is written  $v^a$ . In coordinates  $(x^1, \ldots, x^n)$  this means functions  $(v^1, \ldots, v^n)$  with  $v = v^1 \frac{\partial}{\partial x^1} + \cdots + v^n \frac{\partial}{\partial x^n}$ .

#### Example

An *I-form* on X is a tensor  $\alpha_{b_1 \cdots b_l}$  with

 $\alpha_{b_1 \cdots b_{i-1} b_j b_{i+1} \cdots b_{j-1} b_i b_{j+1} \cdots b_l} = -\alpha_{b_1 \cdots b_l}$  for all  $1 \leq i < j \leq l$ . So a 2-form is  $\alpha_{ab}$  with  $\alpha_{ba} = -\alpha_{ab}$ .

#### Example

A Riemannian metric is a tensor  $g_{ab}$  with  $g_{ab} = g_{ba}$ , with  $(g_{ab})_{a,b=1,...,n}$  a positive definite  $n \times n$  matrix of functions.

Index notation makes it easy to describe (anti)symmetries of tensors, by permuting indices.

Lecture 3: Tensors

## The Einstein summation convention

Dominic Joyce, Oxford University

As TX,  $T^*X$  are dual, there is a dual pairing  $TX \times T^*X \to \mathbb{R}$ . This induces vector bundle morphisms  $\bigotimes^{k+1} TX \otimes \bigotimes^{l+1} T^*X \to \bigotimes^k TX \otimes \bigotimes^l T^*X$  by contracting together a TX and a  $T^*X$  factor (need to specify which factors). In index notation, this is done by the *Einstein summation convention*: if an index *c* occurs twice in a tensor in a formula, once as an upper and once as a lower index, then (thinking in terms of tuples of functions) we are to sum the index *c* from  $1, \ldots, n = \dim X$ , even though the sum  $\sum_{c=1}^{n}$  is not written.

1 9 Q (P

#### Example

Let  $v \in C^{\infty}(TX)$  be a vector field, and  $\alpha \in C^{\infty}(T^*X)$  a 1-form. In index notation we write  $v = v^a$ ,  $\alpha = \alpha_b$ . Then  $v^a \alpha_b$  in index notation means  $v \otimes \alpha \in C^{\infty}(TX \otimes T^*X)$ . But  $v^a \alpha_a$  means the smooth function  $\alpha(v) : X \to \mathbb{R}$ . In coordinates,  $v^a \alpha_a$  means  $v^1 \alpha_1 + \cdots + v^n \alpha_n$ .

#### Example

Let  $v, w \in C^{\infty}(TX)$  be vector fields, and  $g \in C^{\infty}(S^2T^*X)$  a Riemannian metric. Then  $v = v^a$ ,  $w = w^b$ ,  $g = g_{ab}$  in index notation, and  $g_{ab}v^aw^b$  means the function g(v, w), the inner product of v, w using g, and  $g_{ab}v^av^b$  means the function  $|v|^2$ .

Tensors Exterior forms Some linear algebra Operations on vector bundles; tensor Index notation for tensors The Lie bracket of vector fields Exponentiating vector fields

## 3.4. The Lie bracket of vector fields

In the next sections we will discuss various ways in which we can *differentiate* tensors, or more general sections of vector bundles. One of the simplest of these is the Lie bracket of vector fields.

#### Definition

Let X be a manifold, and  $v, w \in C^{\infty}(TX)$  be vector fields on X. We will define a vector field  $[v, w] \in C^{\infty}(TX)$  called the Lie bracket of v and w. In local coordinates  $(x^1, \ldots, x^n)$  on  $U \subseteq X$ , this is given in index notation by the formula

$$[v,w]^{a} = v^{b} \frac{\partial w^{a}}{\partial x^{b}} - w^{b} \frac{\partial v^{a}}{\partial x^{b}}.$$
(3.3)

ヘロト ヘヨト ヘヨト ヘヨト

500

That is, if 
$$v = v^1 \frac{\partial}{\partial x^1} + \dots + v^n \frac{\partial}{\partial x^n}$$
 and  $w = w^1 \frac{\partial}{\partial x^1} + \dots + w^n \frac{\partial}{\partial x^n}$ ,  
then  $[v, w] = u^1 \frac{\partial}{\partial x^1} + \dots + u^n \frac{\partial}{\partial x^n}$ , where  
 $u^a = \sum_{b=1}^n v^b \frac{\partial w^a}{\partial x^b} - w^b \frac{\partial v^a}{\partial x^b}$ . (3.4)

#### Exercise 3.1

Show that the Lie bracket [v, w] in (3.3) is well-defined. That is, as a vector field it is independent of the choice of local coordinates  $(x^1, \ldots, x^n)$  used to define it.

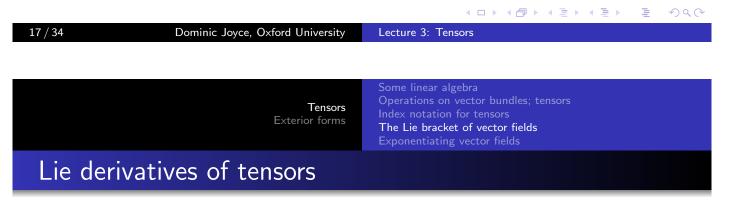

#### Proposition 3.2

The Lie bracket of vector fields satisfies [u, v] = -[v, u] and

$$[u, [v, w]] + [v, [w, u]] + [w, [u, v]] = 0$$
(3.5)

for all vector fields  $u, v, w \in C^{\infty}(TX)$ .

Equation (3.5) is called the *Jacobi identity*. It means that vector fields  $C^{\infty}(TX)$  are an (infinite-dimensional) Lie algebra.

#### Definition

Let X be a manifold,  $v \in C^{\infty}(TX)$  be a vector field, and  $T \in C^{\infty}(\bigotimes^{k} TX \otimes \bigotimes^{l} T^{*}X)$  a tensor. We will define a tensor  $\mathcal{L}_{v}T \in C^{\infty}(\bigotimes^{k} TX \otimes \bigotimes^{l} T^{*}X)$  called the *Lie derivative of* T *along* v. In local coordinates  $(x^{1}, \ldots, x^{n})$  on  $U \subseteq X$ , this is given in index notation by the formula

$$(\mathcal{L}_{v}T)_{b_{1}\cdots b_{l}}^{a_{1}\cdots a_{k}} = v^{c}\frac{\partial}{\partial x^{c}}T_{b_{1}\cdots b_{l}}^{a_{1}\cdots a_{k}} - \sum_{i=1}^{k}T_{b_{1}\cdots b_{l}}^{a_{1}\cdots a_{i-1}ca_{i+1}\cdots a_{k}}\frac{\partial v^{a_{i}}}{\partial x^{c}} + \sum_{j=1}^{l}T_{b_{1}\cdots b_{j-1}cb_{j+1}\cdots b_{l}}^{a_{1}\cdots a_{k}}\frac{\partial v^{c}}{\partial x^{b_{j}}}.$$
(3.6)

This is well-defined, i.e. independent of the choice of coordinates  $(x^1, \ldots, x^n)$ . If T = w is a vector field then  $\mathcal{L}_v w = [v, w]$ .

・ロト・日本・モート・ロー うくの

We can think of  $\mathcal{L}_v T$  as 'the derivative of T in the direction v'. But note that (3.6) involves derivatives of v as well as T, so  $\mathcal{L}_v T$  is not pointwise linear in v. That is, in general  $\mathcal{L}_{fv+gw}T \neq f\mathcal{L}_v T + g\mathcal{L}_w T$  for vector fields v, w and functions  $f, g: X \to \mathbb{R}$ .

#### Example

In coordinates  $(x^1, \ldots, x^n)$ , take  $v = \frac{\partial}{\partial x^i}$ , so that  $v^1, \ldots, v^n$  are  $v^a = 1$  for a = i and  $v^a = 0$  otherwise. Then (3.6) becomes

$$(\mathcal{L}_{v}T)^{a_{1}\cdots a_{k}}_{b_{1}\cdots b_{l}}=\frac{\partial}{\partial x^{i}}T^{a_{1}\cdots a_{k}}_{b_{1}\cdots b_{l}},$$

as you would expect.

## 3.5. Exponentiating vector fields

Let X be a compact manifold (for simplicity), and  $v \in C^{\infty}(TX)$  a vector field. A *flow-line* of v is a smooth map  $\gamma : \mathbb{R} \to X$  satisfying the differential equation  $\frac{d\gamma}{dt}(t) = v|_{\gamma(t)} \in T_{\gamma(t)}V$  for all  $t \in \mathbb{R}$ . Results on o.d.e.s imply that for each  $x \in X$ , there is a unique flow-line  $\gamma_x$  with  $\gamma_x(0) = x$ . Here we need X compact so that flow-lines cannot 'fall off the edge of X', so that  $\gamma$  could only be defined on an open interval, not all of  $\mathbb{R}$ . (Consider X = (0, 1), noncompact and  $v = \frac{\partial}{\partial x}$ . Then  $\gamma$  is only defined on (-x, 1 - x).) Define  $\exp(tv) : X \to X$  for  $t \in \mathbb{R}$  by  $\exp(tv) : x \mapsto \gamma_x(t)$ , for  $\gamma_x$  the flow-line of v with  $\gamma_x(0) = x$  as above. Then  $\exp(tv)$  is a diffeomorphism of X depending smoothly on t, with  $\exp(0) = \operatorname{id}_X$  and  $\exp(sv) \circ \exp(tv) = \exp((s+t)v)$  for  $s, t \in \mathbb{R}$ .

If  $T \in C^{\infty}(\bigotimes^{k} TX \otimes \bigotimes^{l} T^{*}X)$  is a tensor on X, then  $\exp(tv)^{*}(T)$  is a tensor depending smoothly on  $t \in \mathbb{R}$ . One can show that  $\mathcal{L}_{v}T = \frac{\mathrm{d}}{\mathrm{d}t} \left[\exp(tv)^{*}(T)\right]\Big|_{t=0}.$ 

That is,  $\mathcal{L}_v T$  measures the infinitesimal change of T under the flow of v.

# 4. Exterior forms4.1. Exterior forms and the de Rham differential

Let X be a manifold, of dimension n. Then we have vector bundles  $\Lambda^k T^*X$  for k = 0, 1, ..., n (note that  $\Lambda^k T^*X = 0$  for k > n). Sections  $\alpha$  of  $\Lambda^k T^*X$  are called *k*-forms, and form a (generally infinite-dimensional) vector space  $C^{\infty}(\Lambda^k T^*X)$ . In index notation  $\alpha = \alpha_{a_1 \cdots a_k}$ , and is antisymmetric in the indices  $a_1, ..., a_k$  (i.e. if you exchange any two  $a_i, a_j$ , you change the sign). As in §3.1–§3.2 we have the *exterior product* (wedge product)

 $\wedge: C^{\infty}(\Lambda^{k}T^{*}X) \times C^{\infty}(\Lambda^{l}T^{*}X) \longrightarrow C^{\infty}(\Lambda^{k+l}T^{*}X),$ 

acting in index notation by

$$(\alpha \wedge \beta)_{\mathbf{a}_1 \cdots \mathbf{a}_{k+l}} = \frac{1}{(k+l)!} \sum_{\sigma \in S_{k+l}} \operatorname{sign}(\sigma) \alpha_{\mathbf{a}_{\sigma(1)} \cdots \mathbf{a}_{\sigma(k)}} \beta_{\mathbf{a}_{\sigma(k+1)} \cdots \mathbf{a}_{\sigma(k+l)}}.$$
(4.1)

Exterior forms and the de Rham differential Homology and cohomology Examples

## Pullback of forms by smooth maps

Let  $f: X \to Y$  be a smooth map of manifolds. As in §2.2 we have  $Tf: TX \to TY$ , which can be interpreted as a vector bundle morphism  $df: TX \to f^*(TY)$  on X, with a dual morphism  $(df)^*: f^*(T^*Y) \to T^*X$ . Taking exterior powers gives vector bundle morphisms on X

$$\Lambda^k(\mathrm{d} f)^*:f^*(\Lambda^kT^*Y)\longrightarrow \Lambda^kT^*X.$$

Let  $\alpha \in C^{\infty}(\Lambda^{k}T^{*}Y)$  be a k-form on Y. Then we have a pullback  $f^{-1}(\alpha) \in C^{\infty}(f^{*}(\Lambda^{k}T^{*}Y))$  on X. Define the *pullback k-form* to be  $f^{*}(\alpha) = \Lambda^{k}(df)^{*}[f^{-1}(\alpha)] \in C^{\infty}(\Lambda^{k}T^{*}X).$ 

Pullback is (contravariantly) functorial,  $(g \circ f)^*(\beta) = f^* \circ g^*(\beta)$ for smooth  $g: Y \to Z$  and  $\beta \in C^{\infty}(\Lambda^k T^*Z)$ .

If  $X \subseteq Y$  is a submanifold, we write  $\alpha|_X$  for  $i^*(\alpha)$ , with  $i : X \hookrightarrow Y$  the inclusion.

Tensors Exterior forms Exterior forms and the de Rham differential Homology and cohomology Examples

#### Definition

The de Rham differential  $d: C^{\infty}(\Lambda^k T^*X) \longrightarrow C^{\infty}(\Lambda^{k+1}T^*X)$  for  $k \ge 0$  is defined in local coordinates  $(x^1, \ldots, x^n)$  on  $U \subseteq X$ , using index notation, by the formula

$$(\mathrm{d}\alpha)_{a_1\cdots a_{k+1}} = \sum_{i=1}^{k+1} (-1)^{i-1} \frac{\partial}{\partial x^{a_i}} \alpha_{a_1\cdots a_{i-1}a_{i+1}\cdots a_{k+1}}.$$
 (4.2)

#### Exercise 4.1

Show that the de Rham differential is well-defined. That is, as a k + 1-form,  $d\alpha$  is independent of the choice of local coordinates  $(x^1, \ldots, x^n)$  used to define it.

## Properties of the de Rham differential

From equations (4.1) and (4.2) we can prove:

Proposition 4.2

For all forms  $\alpha, \beta, \gamma$  on X, the de Rham differential satisfies

$$d \circ d\alpha = 0, \quad d(\beta \wedge \gamma) = (d\beta) \wedge \gamma + (-1)^{\deg \beta} \beta \wedge (d\gamma).$$
 (4.3)

Proposition 4.3

Let  $f : X \to Y$  be smooth map of manifolds and  $\alpha \in C^{\infty}(\Lambda^k T^*Y)$ . Then  $d(f^*(\alpha)) = f^*(d\alpha)$ .

## 4.2. Homology and cohomology

A reminder of some algebraic topology: let X be a topological space, and F a field (for simplicity). Then we can define the homology groups  $H_k(X, \mathbb{F})$  and cohomology groups  $H^k(X, \mathbb{F})$  for  $k \in \mathbb{N}$ , which are vector spaces over F, with  $H^k(X, \mathbb{F}) \cong H_k(X, \mathbb{F})^*$ If  $f : X \to Y$  is continuous there are functorial pushforward maps  $f_* : H_k(X, \mathbb{F}) \to H_k(Y, \mathbb{F})$  on homology, and pullback maps  $f^* : H^k(Y, \mathbb{F}) \to H^k(X, \mathbb{F})$  on cohomology. There are cup products  $\cup : H^k(X, \mathbb{F}) \times H^l(X, \mathbb{F}) \to H^{k+l}(X, \mathbb{F})$  making  $H^*(X, \mathbb{F})$  into a supercommutative graded algebra. If X is a compact, oriented manifold of dimension n, then Poincaré duality says that  $H^k(X, \mathbb{F}) \cong H_{n-k}(X, \mathbb{F})$ . The Betti numbers of X are  $b^k(X) = \dim H^k(X, \mathbb{R})$ . Homology and cohomology are important topological invariants of a space, one of the most basic things you can compute.

## De Rham cohomology

## Definition

Let X be a smooth manifold. The *de Rham cohomology group*  $H^k_{dR}(X, \mathbb{R})$  of X, for  $k = 0, ..., \dim X$ , is

$$H^k_{\mathrm{dR}}(X,\mathbb{R}) = \frac{\mathrm{Ker}\big(\mathrm{d}: C^\infty(\Lambda^k T^*X) \longrightarrow C^\infty(\Lambda^{k+1} T^*X)\big)}{\mathrm{Im}\big(\mathrm{d}: C^\infty(\Lambda^{k-1} T^*X) \longrightarrow C^\infty(\Lambda^k T^*X)\big)} \,.$$

This makes sense as  $d \circ d = 0$ , by Proposition 4.2. The second equation of (4.3) implies that we can define a *cup product* 

$$\cup : H^k_{\mathrm{dR}}(X,\mathbb{R}) \times H^l_{\mathrm{dR}}(X,\mathbb{R}) \longrightarrow H^{k+l}_{\mathrm{dR}}(X,\mathbb{R}), \\ (\beta + \mathrm{Im}\,\mathrm{d}) \cup (\gamma + \mathrm{Im}\,\mathrm{d}) \longmapsto \beta \wedge \gamma + \mathrm{Im}\,\mathrm{d},$$

which is associative and supercommutative as  $\wedge$  is. If X is compact then  $H^k_{dR}(X, \mathbb{R})$  is finite-dimensional.

29 / 34	Dominic Joyce, Oxford University	Lecture 4: Exterior forms
	Tensors Exterior forms	Exterior forms and the de Rham differential Homology and cohomology Examples

If  $f : X \to Y$  is a smooth map of manifolds then Proposition 4.3 implies that we can define *pullback maps* 

$$f^*: H^k_{\mathrm{dR}}(Y, \mathbb{R}) \longrightarrow H^k_{\mathrm{dR}}(X, \mathbb{R}), \quad f^*(\alpha + \mathrm{Im}\,\mathrm{d}) = f^*(\alpha) + \mathrm{Im}\,\mathrm{d}.$$

These pullback maps are independent of  $f: X \to Y$  up to smooth (or continuous) deformation. That is, if  $g: X \times [0,1] \to Y$  is smooth and  $f_0, f_1: X \to Y$  are  $f_0(x) = g(x,0), f_1(x) = g(x,1)$ then  $f_0^* = f_1^*: H^k_{dR}(Y, \mathbb{R}) \to H^k_{dR}(X, \mathbb{R}).$ 

#### Theorem (The de Rham Theorem)

There are natural isomorphisms  $H^k_{dR}(X, \mathbb{R}) \cong H^k(X, \mathbb{R})$ , where  $H^k(X, \mathbb{R})$  is the  $k^{th}$  real cohomology group of the underlying topological space X. These isomorphisms are compatible with cup products and pullbacks on  $H^*_{dR}(-, \mathbb{R})$  and  $H^*(-, \mathbb{R})$ .

Exterior forms and the de Rham differential Homology and cohomology Examples

## Cohomology of products, the Künneth Theorem

Let X, Y be topological spaces, and  $\mathbb{F}$  a field. We have a product topological space  $X \times Y$  with projections  $\pi_X : X \times Y \to X$ ,  $\pi_Y : X \times Y \to Y$ .

Theorem (The Künneth Theorem)  
For each 
$$k \ge 0$$
 there is an isomorphism  

$$\bigoplus_{i,j\ge 0:i+j=k} H^i(X,\mathbb{F}) \otimes_{\mathbb{F}} H^j(Y,\mathbb{F}) \longrightarrow H^k(X \times Y,\mathbb{F})$$
acting by  $\bigoplus_{i+j=k} \alpha^i \otimes \beta^j \longmapsto \sum_{i+j=k} \pi_X^*(\alpha^i) \cup \pi_Y^*(\beta^j)$ , for  
 $\alpha^i \in H^i(X,\mathbb{F})$  and  $\beta^j \in H^j(Y,\mathbb{F})$ .  
In particular, this applies to de Rham cohomology of products of

In particular, this applies to de Rham cohomology of products of manifolds.

## Betti numbers and the Euler characteristic

Dominic Joyce, Oxford University

Let X be a manifold (usually compact). The Betti numbers of X are  $b^k(X) = \dim H^k_{dR}(X, \mathbb{R})$ . The Euler characteristic is  $\chi(X) = \sum_{k=0}^{\dim X} (-1)^k b^k(X)$ . They are topological invariants of X. If X is compact then  $H^k_{dR}(X, \mathbb{R})$  is finite-dimensional, so these are well defined. If X is compact and odd-dimensional then  $\chi(X) = 0$ . The Künneth Theorem implies that  $\chi(X \times Y) = \chi(X)\chi(Y)$ . The Euler characteristic is very important, and crops up in many different places. For example, if X is a compact manifold then the number of zeroes of a generic vector field v on X, counted with multiplicity, is  $\chi(X)$ . The Gauss-Bonnet Theorem says that if (X, g) is a compact Riemannian 2-manifold with Gaussian curvature  $\kappa$  then

 $\int_X \kappa \,\mathrm{d} V_g = 2\pi \chi(X).$ 

#### Tensors Exterior forms

Dominic Joyce, Oxford University

Exterior forms and the de Rham differential Homology and cohomology Examples

## 4.3. Examples

#### Example

33 / 34

The de Rham cohomology of  $\mathbb{R}^n$  for  $n \ge 0$  is  $H_{dR}^k(\mathbb{R}^n, \mathbb{R}) = \begin{cases} \mathbb{R}, & k = 0, \\ 0, & k > 0. \end{cases}$ When n = 0, so that  $\mathbb{R}^0 = *$  is a point, this is immediate from the definitions. To prove it when n > 0, consider the smooth maps  $i : * \to \mathbb{R}^n$ ,  $i : * \mapsto (0, \dots, 0)$ , and  $\pi : \mathbb{R}^n \to *$ ,  $\pi : (x_1, \dots, x_n) \mapsto *$ . These induce maps  $i^* : H_{dR}^k(\mathbb{R}^n, \mathbb{R}) \to H_{dR}^k(*, \mathbb{R})$  and  $\pi^* : H_{dR}^k(*, \mathbb{R}) \to H_{dR}^k(\mathbb{R}^n, \mathbb{R})$ . Since  $\pi \circ i = \mathrm{id} : * \to *$  we see that  $i^* \circ \pi^*$  is the identity on  $H_{dR}^k(*, \mathbb{R})$ . Conversely, although  $i \circ \pi \neq \mathrm{id} : \mathbb{R}^n \to \mathbb{R}^n$ , we can smoothly deform  $i \circ \pi$  to id, so  $\pi^* \circ i^*$  is the identity on  $H_{dR}^k(\mathbb{R}^n, \mathbb{R})$ . Hence  $i^*, \pi^*$  are inverse, and  $H_{dR}^k(\mathbb{R}^n, \mathbb{R}) \cong H_{dR}^k(*, \mathbb{R})$ .

Lecture 4: Exterior forms

Tensors Exterior forms Examples Example The de Rham cohomology of  $S^n$  for n > 0 is  $\mathcal{H}^k_{\mathrm{dR}}(\mathcal{S}^n,\mathbb{R})\congegin{cases}\mathbb{R},&k=0 ext{ or }k=n,\0,& ext{ otherwise.}\end{cases}$ (4.5)Example The de Rham cohomology of  $T^n$  for  $n \ge 0$  is  $H^k_{\mathrm{dB}}(T^n,\mathbb{R})\cong\mathbb{R}^{\binom{n}{k}}.$ This follows from (4.5) for  $H^*_{dR}(\mathcal{S}^1, \mathbb{R})$  and the Künneth Theorem. Considering  $H^1_{dR}(-,\mathbb{R})$  we see that: Corollary There is no diffeomorphism  $S^n \cong T^n$  for  $n \ge 2$ . De Rham cohomology is useful for distinguishing manifolds. 500 Dominic Joyce, Oxford University Lecture 4: Exterior forms 34 / 34
